

Mathematical Analysis Lecture 36 级数.

e.g. $\sum_{n=1}^{\infty} \frac{1}{n^3+3n^2+2n} = \sum_{n=1}^{\infty} \frac{1}{n(n+2)(n+1)} \leq \sum_{n=1}^{\infty} \frac{1}{n(n+1)}$ 必然收敛.

$$= \frac{n+2-n}{n(n+1)(n+2)} \cdot \frac{1}{2} = \frac{1}{2} \left(\frac{1}{n(n+1)} - \frac{1}{(n+1)(n+2)} \right) = \frac{1}{2} \left[\left(\frac{1}{n} - \frac{1}{n+1} \right) - \left(\frac{1}{n+1} - \frac{1}{n+2} \right) \right]$$

$$\therefore \sum_{n=1}^{\infty} \frac{1}{n^3+3n^2+2n} = \frac{1}{4}$$

e.g. $\sum_{n=1}^{\infty} \frac{2n-1}{2^n}$, $S_n - \frac{1}{2}S_n = \left(\frac{1}{2} + \frac{3}{2^2} + \frac{5}{2^3} + \dots \right) - \left(\frac{1}{2^2} + \frac{3}{2^3} + \frac{5}{2^4} + \dots \right)$

$$= \frac{1}{2} + \frac{1}{2} + \frac{1}{2^2} + \frac{1}{2^3} = \frac{3}{2} \quad \therefore \frac{1}{2}S_n = \frac{3}{2} \quad S_n = 3 \quad \text{收敛}$$

e.g. $\sum_{n=1}^{\infty} \arctan \frac{1}{2n^2}$, $\because \arctan x - \arctan y = \arctan \frac{x-y}{1+xy}$

$$\therefore \arctan \frac{1}{2n^2} = \arctan \frac{1}{2n-1} - \arctan \frac{1}{2n+1} \quad \therefore \text{原} = \frac{\pi}{4}$$

无穷级数的基本性质:

线性 { 性质1: 若 $\sum_{n=1}^{\infty} u_n$ 收敛于 S , 则 $\sum_{n=1}^{\infty} cu_n = cS$, $c \in \mathbb{R}$.
级数各项乘以非零常数后收敛性不变.

性质2: 假设有2个收敛级数 $S = \sum_{n=1}^{\infty} u_n$, $\sigma = \sum_{n=1}^{\infty} v_n$. $\therefore \sum_{n=1}^{\infty} (u_n \pm v_n) = S \pm \sigma$.

性质3: 去除有限项或加入有限项, 不影响收敛性.

性质4: 收敛级数加括号后形成的级数收敛于原级数的和.

证: 设 $S_n = \sum_{n=1}^n u_n$ 按某一规律加括号, 其部分和序列 σ_m 为原级数为原数列的子列. $\therefore \lim_{m \rightarrow +\infty} \sigma_m = \lim_{n \rightarrow +\infty} S_n = S$.

推论: 若加了括号后的级数发散, 则原级数必发散.

例: 收敛级数去括号后的级数不一定收敛 $(1-1) + (1-1) + \dots \neq 1-1+1-1+\dots$, 前者收敛, 后者发散.

Cauchy 收敛原理:

"一个级数 $\sum_{n=1}^{\infty} u_n$ 收敛的充要条件是: $\forall \varepsilon > 0$, $\exists N \in \mathbb{N}_+$, 当 $n > N$ 时, $\forall p > N$, 有 $|u_{n+1} + u_{n+2} + \dots + u_{n+p}| < \varepsilon$."

证: $|u_{n+1} + u_{n+2} + \dots + u_{n+p}| = |S_{n+p} - S_n| < \varepsilon$. 利用数列的柯西收敛原理:
